#### Abstract

Fracture clavicle in adults is common, treatment of such fracture is debatable, and in case of surgical treatment, the method of fixation is also debatable. In the current study, we reviewed the literature to bring up the answers for this debatable point, and to focus on the positive and negative results of surgical plating for the fracture clavicle in adults. The search was performed in the following electronic databases: PubMed, SCOPUS, Web of Science, and The Cochrane Library. The search included key words of: clavicle, fracture clavicle, in association with surgical approaches, plating of the clavicle and functional ability or physical activity. The initial search in database yielded 98 articles which match the search key words, by 1st screening, 47 articles were removed as duplicated titles and articles not in English language, 51 articles were re-screened, 40 articles were excluded as they were case reports, studies with unclear description of the outcome and unfound articles, and the remaining articles for final analysis were 11 articles. We recommended using of locking precontoured plate for fixation of the clavicle fractures especially middle third, and anteroinferior approach to perform this fixation; by combination of both, it will be of little complication and high successful rate of union.

Keywords Clavicle fracture · Plate · Surgical

## Introduction

One of the commonest fractures is fracture clavicle; it represents 2.6 to 10% of all fractures and about 35 to 45% of shoulder injuries, in addition 2 to 5% of total adult fractures [1, 2].

Regarding the site of fracture, it was reported that the mid shaft fractures are the commonest, 70%, while the medial third fractures are the lowest, 2 to 3%, where the lateral third fracture accounts 25 to 28%, of all fracture clavicle [2]

<sup>1</sup> Orthopedic Department, Benha Faculty of Medicine, Benha University, El-Shaheed Farid Nada Street, Kafer el gazar, Banha 13511, Qalyubia, Egypt Trauma is considered the most common cause of facture clavicle, direct fall on the shoulder, 87%, direct fall on outstretched hand, 6%, and direct trauma to the clavicle, 7%, while pathological or stress fractures are rare causes [3].

The treatment of fracture clavicle whether conservative or operative is still a challenge; the indication of surgery in patients with facture clavicle includes the need for rapid and early mobilization of the shoulder, open fracture, flail shoulders and polytrauma patients [4].

There are variable methods of fixation and variable surgical approaches for operative treatment of fracture clavicle [4]. In the current study, we reviewed the different indications and techniques of plating of clavicular fractures also the results and the complications of each technique.

# **Materials and Methods**

### **Data Sources and Search Strategy**

The search was performed in the following electronic databases: PubMed, SCOPUS, Web of Science, and The Cochrane Library. The search key words were: clavicle,

fracture clavicle, in association with surgical approaches, plating of the clavicle and functional ability or physical activity.

- Clinical studies with patients of fracture clavicle.
- Fracture clavicle underwent surgical intervention by plating.
- Articles in English language.

All selected titles are screened to meet the following criteria:

**Selection of Studies and Screening of Titles** 

**Fig. 2** Mean age years of patients of enrolled studies of different authors (n = 2370)

and Abstracts

**Fig. 3** Sex of the enrolled studied patients of different authors studies (n = 2370)

**Fig. 4** Sex of the total enrolled studied patients (n = 689)

## **Study Characteristics**

The data extraction was performed to obtain the name of the authors, year of publication, types of the plate, the number of patients in each group, age, sex (Figs. 1, 2, 3, and 4), and duration of the follow-up, surgical, and functional outcomes of each intervention (Tables 1 and 2).

# **Outcomes of the Included Studies**

The outcome included complications, rate of bony union, advantages of each surgical intervention, and radiological outcome of each method of intervention (Table 3).

## **Inclusion Criteria**

Studies which met these inclusion criteria were considered for the final analysis in the current study:

- 1) Fracture clavicle in adult.
- 2) Open reduction and internal fixation by plate and screws.
- 3) Follow-up duration more than 12 months.
- 4) Age group 18–60 years old.
- 5) Studies using different types of plates.
- 6) Studies using different approaches to the fracture.

Exclusion criteria:

- 1) Studies with languages rather than English.
- 2) Studies with unclear description of results and techniques.

3) Follow-up duration less than 1 year.

4) Experimental and cadaveric studies.

### Literature Search (Selection of Studies)

The initial search in database yielded 98 articles which match the search key words, by 1st screening, 47 articles were removed as duplicated titles and articles not in English language, 51 articles were re-screened, 40 articles were excluded as they were case reports, studies with unclear

# Discussion

Several authors had recommended surgical intervention for displaced fracture clavicle with liability for skin penetration, impaired neurovascular, open fractures, patient with poly trauma, and floating shoulder as absolute indication, while nonunion is considered a relative indication for surgical intervention [16].

Many authors advocated that plate osteosynthesis is the standard tool for operative treatment of the fracture clavicle; there are many types of plates as dynamic compression, locked, and reconstruction plates [16, 17].

Recent studies had recommended of open reduction and plate fixation of the mid shaft and lateral fractures of the clavicle to avoid nonunion or mal union of these fractures [7]. Hill et al. had treated 52 patients with displaced fracture clavicle conservatively, 15% had nonunion, and 31% were not satisfied functionally [18]. Zlowodzki et al. had reviewed 2144 midshaft clavicle fractures and they found that 15.1% had nonunion [19], while McKee et al. [20] had evaluated 30 patients of mid shaft fracture clavicle who were treated conservatively; they found that the mean constant score 71 Table 7Different approaches,and plating of fracture withimplant failure proportionamong the enrolled studiedpatients

irritation and failure [21], while Wang et al. had found that most of the patients who were treated by precontoured plating for mid shaft fracture clavicle were discomfort and prefer for implant removal because of implant prominence and irritation [22]. In the current study, the most common mechanisms of injury were motor vehicle accident, road traffic accident, sports injury, bicycle related trauma, and falling from height (Table 3) (Figs. 5 and 6). Regarding bony union, we had found that union rate was 97.5% (2310 patients) (Figs. 7 and

SN Operations Research Forum

9) while the remaining 2.5% of the whole cases (60 patients) developed nonunion (Figs. 8 and 9) and required another surgery with bone graft which was not briefly discussed by most authors so we could not document that in our study. In addition, we found that malunion can occur secondary to

poor plating technique or a loss of reduction postoperatively (Table 5).

One of the most serious complications in this review is implant failure in the form of screw breakage or implant loosening which subsequently affects the reduction of the

**Fig. 7** Proportion of union after plating among the enrolled studied patients in relation to approach

fracture (Figs. 10, 11, and 12). Hulsmans [6] has the most frequency of implant failure in his study (Table 7).

approach

Infection is a very serious complication in the orthopedic surgeries. In fracture clavicle fixed with plates, infection is common due to the subcutaneous position of the implant and poor soft tissue coverage [9]. In this review, two authors, Lee [11] and Chen [12], did not document the infection rate of

Fig. 9 Total proportion of union and nonunion after plating among the enrolled studied patients (n = 2370)

```
SN Operations Research Forum
                A SPRINGER NATURE journal
```

their cases. So, the total patient number to study the infection rate will be 2176 patient. The number of infected cases (in the form of wound dehiscence or pus discharge) is 108 patients (4.96%), most of them with the superior approach (9.9%) and with the locking precontoured plate (5.8%)(Figs. 13, 14, and 15). All of these cases were controlled by medical treatment and none of them required a secondary surgery (Table 8).

Regarding the surgical approach, we have found that anterior inferior approach (Figs. 6 and 16) was used in 5 studies with total patient number 1440. It is considered one of the best approaches used in the review with the least complication rate (in relation to implant failure and infection) and good union rate (96.8%), while the superior approach was used in 6 studies with total patient number 669. Easy approach to use for fracture reduction and plate fixation. Despite the best union rate (98.6%), it has a very high complication rate according to implant failure (13.7%) and infection rate (9.9%), where direct transverse approach was used in 4 studies with total patient number 240. It is a direct incision across the fracture. Union rate is 98.3%. This approach has the highest implant failure rate by 14.6% and infection rate 2.9% (Table 4 and Table 9).

Minimally invasive plate osteosynthesis (MIPO) was used in only one study with total patient number 21. A difficult surgical approach in controlling the fracture but it preserves

Fig. 11 Implant failure proportion among the enrolled studied patients of different authors in relation to type of plate (n = 2370)

Fig. 12 Total implant failure proportion among the enrolled studied patients of different authors (n = 2370)

the vascularity of the clavicle. Union rate was 95.2%. None of the cases has been infected but there is only one case (4.8%) with implant failure (Table 7).

reconstruction plate was used in 3 cases series with total patient number 385 and with union rate 98.4%. It was the first plate to be used in the fixation of fracture clavicle but it shows high complication rate. In this study, it has the highest rate of implant failure 16.9% and the infection rate was 2.3%, while locking reconstruction plate was used in 3 papers with total patient number 295 and with union rate 95.9%. It provides more rigid fixation than the non-locking reconstruction plate specially with comminuted fractures so implant failure rate is lower (13.9%) but the infection rate is higher than that of the non-locking reconstruction plate (4.1%) (Table 7).

On the other hand, we have found that locking precontoured plate was used in 3 studies with total patient number 1591 and with union rate 97.5%. It is now the most common plate used in fixation of clavicle fractures specially the middle third fractures. The implant failure rate is 4.5% and the infection rate is 5.8% which is the highest rate of infection among all studies in this review (Table 7).

Hook plate, a special plate for the lateral third clavicular fractures, was used in 2 studies with total patient number 67 and with union rate 98.5%. None of the cases has got infection but there is only one case (1.5%) with implant failure (Table 7).

Locking plate with lateral extension, also a special plate for the lateral third clavicular fractures as the hook plate,

Regarding type of plates used in the treatment of fracture clavicle (Fig. 17), it was found that non-locking

was used in one case series with total patient number 32 and with union rate 96.9%. None of the cases has got infection or

SN Operations Research Forum

Fig. 13 Proportion of postoperative infection after plating among the enrolled studied patients in relation to approach (n = 2176)

implant failure. It is just one patient (3.1%) with nonunion (Table 7 and Table 10).

The current study does have some limitations. The direct transverse approach is not as frequently described in the

literature, and there is only one study that compare between MIPO and open technique in fracture fixation; the study presents different surgeons with different plate application which affects the outcome (Table 11).

## Conclusion

From this review, we recommended using of locking precontoured plate for fixation of the clavicle fractures especially middle third, and anteroinferior approach to perform this fixation; by combination of both, it will be of little complication and high successful rate of union.
